Electric lamp

The invention relates to an electric lamp comprising a light-transmitting lamp vessel in which a light source is arranged,

said electric lamp comprising a light-absorbing medium exhibiting a spectral transition in the visible range,

5 the spectral transmission T of light transmitted by the light-absorbing medium changes from $T \leq 0.15$ to $T \geq 0.75$ in a wavelength range having a width $\lambda \leq 100$ nm,

at least a part of the lamp vessel being provided with an interference film.

Such lamps are used in automotive applications, for example as a (halogen) headlamp that, in operation, emits yellow light, as an amber-colored light source in indicators
10 (also referred to as vehicle signal lamps) or as a red-colored light source in brake lights. Such electric lamps are also used for general illumination purposes. Said electric lamps are further used in traffic and direction signs, contour illumination, traffic lights, projection illumination and fiber optics illumination. Alternative embodiments of such lamps comprise lamps wherein the color temperature is increased by means of a suitable combination of a light-
15 absorbing coating and an interference film.

An electric lamp of the type mentioned in the opening paragraph is known from WO 01/97253. In said known electric lamp the light-absorbing medium exhibits a
20 comparatively steep spectral transition in the visible range. The application of a light-absorbing medium having such a comparatively steep spectral characteristic in an electric lamp whose lamp vessel is provided with an interference film results in an electric lamp having an improved color-neutral appearance. The electric lamp is provided with an interference film having an at least substantially flat reflection spectrum over at least
25 substantially the entire visible region. To achieve this, the electric lamp according to WO 01/97253 has a variation in the reflection R of the interference film in the wavelength range from $400 \leq \lambda \leq 690$ nm that is less than 10%. The interference film according to WO 01/97253 comprises at least 5 and at most approximately 17 layers. In operation, the electric lamp emits colored light in the transmission mode and has a substantially color-neutral

appearance in the off state. The appearance of the electric lamp can e.g. be silvery. For this reason said lamps are also referred to as 'silver vision' lamps.

However, a disadvantage of the lamp according to WO 01/97253 is that the silversvision mirror is reflecting both shorter and longer wavelengths, which contribute to the amber emission. This reflections leads to an internal loss that can mount to about 15%. Moreover, the aim according to WO 01/97253 to obtain a substantially flat reflection spectrum in the electric lamp in the wavelength range from $400 \leq \lambda \leq 690$ nm results in color variation. Oscillations are observed which are related to the manufacturing process. These oscillations lead to variation in the external appearance of the lamps from greenish to goldish or purplish reflection.

It is an object of the invention to provide an electric lamp of the type described in the opening paragraph, wherein the above disadvantages are obviated.

This object is achieved, in accordance with the invention, in that the maximum reflection R_{\max} of the interference film lies in the range from $0.50 \leq R_{\max} \leq 0.90$, and in that the variation in the reflection R of the interference film in the wavelength range from $400 \leq \lambda \leq 690$ nm ranges from 0.0 to R_{\max} .

The invention is based on the idea that a color neutral appearance is not restricted to a mirror with a flat reflection characteristic but that the same effect can be obtained with a mirror having a gradual variation in reflectivity, being higher in the green and slightly lower in the adjacent higher and lower wavelength ranges. The resulting interference film is much simpler to manufacture and is also highly reflective and has a color neutral appearance.

Preferably, the variation in the reflection R of the interference film in the wavelength range $400 \leq \lambda \leq 690$ nm ranges from 0.2 to the maximum value for the filter R_{\max} .

It appears that with such variation a color neutral appearance can be obtained.

absorbing medium and an interference film applied to an outside surface of the lamp vessel enables the appearance of the electric lamp to be changed. This particularly enables a distinction to be made between the appearance of the electric lamp in the off state and the color of the light emitted by the electric lamp during operation. The aim is, in particular, to provide an electric lamp that, in operation, emits a certain color, for example a so-called amber-colored or red-colored electric lamp, while, in the off state, the electric lamp has an at least substantially color-neutral appearance.

In vehicles it is desirable, for esthetical reasons, to provide indicator lamps and brake lights with a color-neutral appearance. Only when the electric lamp is activated, it shows the desired color, whereby the color point of the light emitted by the electric lamp meets statutory regulations. Moreover, in vehicles there is a tendency to accommodate amber-colored indicator lamps in the same reflector as the headlamp instead of in a separate reflector. In addition, the aim is to use luminaires in vehicles, which are provided with so-called "clear covers", i.e. an observer situated outside the vehicle can directly see the indicator lamps or brake lamps in the luminaire. For reasons of safety, it is important that, apart from a color-neutral appearance, such indicator lamps are at least substantially free of coloring in reflection at light that is (accidentally) incident on the electric lamp. If, for example, sunlight or light originating from on-coming traffic is incident on a headlamp of a vehicle comprising an indicator lamp, the appearance of said headlamp, in reflection, should be at least substantially colorless or, in reflection, said lamp should emit at least substantially no color. Otherwise, this might confuse other road users and give rise to unsafe and/or undesirable situations.

In reflection, the spectral characteristic of the electric lamp in accordance with the invention differs from the spectral characteristic in transmission. In transmission, the light emitted by the electric lamp meets statutory regulations with respect to the color point, while, in reflection, the electric lamp is color-neutral, the appearance of the electric lamp being, for example, silvery. The current invention applies, in particular, to indicator lamps and brake lights of vehicles.

A synergetic effect is achieved using an electric lamp comprising a combination of a light-absorbing medium with a steep transition and an interference film giving the electric lamp a color-neutral appearance. In addition, the presence of the interference film may increase the stability of the light-absorbing medium in that the interference film serves as an oxygen barrier for the light-absorbing medium. Moreover, the interference film can counteract loss of color of the light-absorbing medium under the

influence of external UV light, for example by a suitable material choice, a suitably chosen band gap (for example TiO_2) or as a result of the fact that the interference film also reflects UV light. Experiments have shown that the adhesion of the combination of light absorbing medium and interference film on the lamp vessel of the electric lamp is satisfactory and not, or hardly, subject to change during the service life. During the service life of the electric lamp in accordance with the invention, no visible delamination of the applied coatings is detected.

An embodiment of an electric lamp in accordance with the invention is characterized in that a wall of the lamp vessel comprises the light-absorbing medium. Light-absorbing media can be readily incorporated in the wall of the lamp vessel, which is made, for example, from glass, such as quartz glass or hard glass, or from a transparent ceramic material. In this embodiment, the interference film is preferably directly applied to a side of the wall of the lamp vessel facing away from the light source. As the light-absorbing medium is provided in the wall of the lamp vessel and the interference film, light, which is reflected by the interference film, passes the light-absorbing medium twice, which leads to a further improvement of the effectiveness of the absorption process. In addition, light that is reflected to and fro between the interference film on both sides of the lamp vessel passes the light-absorbing medium twice at each reflection.

An alternative embodiment of the electric lamp in accordance with the invention is characterized in that the light-absorbing medium comprises a light-absorbing layer that is situated between the lamp vessel and the interference film. As the light-absorbing medium is arranged between the outside surface of the lamp vessel and the interference film, light, which is reflected by the interference film, passes the light-absorbing medium twice, which leads to a further improvement of the effectiveness of the absorption process. In addition, light that is reflected to and fro between the interference film on both sides of the lamp vessel passes the light-absorbing layer twice at each reflection.

A thickness t_{abs} of the light-absorbing layer preferably lies in a range from $5 \text{ nm} \leq t_{\text{abs}} \leq 5000 \text{ nm}$. If the thickness of the light-absorbing layer is smaller than 5 nm, absorption hardly takes place and the intended shift of the color temperature is insufficiently

less and of the order of 10 – 100nm. Examples known to those skilled in the art are the use of sputtered or evaporated Fe_2O_3 layers or layers of similar materials.

In a preferred embodiment, the light-absorbing coating comprises a network, which can be obtained by converting an organically modified silane by means of a sol-gel process, said organically modified silane being selected from the group formed by compounds of the structural formula $\text{R}^{\text{I}}\text{Si}(\text{OR}^{\text{II}})_3$, R^{I} comprising an alkyl group or an aryl group such as CH_3 or C_6H_5 , and R^{II} comprising an alkyl group such as CH_3 or C_2H_5 .

By making the light-absorbing layer from a network comprising an organically modified silane as the starting material, an optically transparent, non-scattering, light-absorbing coating is obtained which is capable of resisting temperatures up to 400 °C. By using an organically modified silane in the manufacture of the network, a part of the R^{I} groups, the alkyl or aryl groups, remains in the network as an end group. As a result, the network does not comprise four network bonds per Si atom, but less than four network bonds per Si atom. In this manner, for example, a network is obtained comprising, on average, approximately three network bonds per Si atom. In spite of the fact that the network is partly composed of said alkyl or aryl groups, a network is obtained whose density is at least substantially equal to that of the customary silica network. Unlike the customary silica network, a network which is partly composed of said alkyl or aryl groups has a greater elasticity and flexibility. As a result, it becomes possible to manufacture comparatively thick light-absorbing coatings.

Particularly suitable starting materials for the manufacture of the network in accordance with the invention are methyltrimethoxysilane (MTMS), wherein $\text{R}^{\text{I}} = \text{R}^{\text{II}} = \text{CH}_3$, methyltriethoxysilane (MTES), wherein $\text{R}^{\text{I}} = \text{CH}_3$ and $\text{R}^{\text{II}} = \text{C}_2\text{H}_5$, phenyltrimethoxysilane (PTMS), wherein $\text{R}^{\text{I}} = \text{C}_6\text{H}_5$ and $\text{R}^{\text{II}} = \text{CH}_3$, and phenyltriethoxysilane (PTES), wherein $\text{R}^{\text{I}} = \text{C}_6\text{H}_5$ and $\text{R}^{\text{II}} = \text{C}_2\text{H}_5$. Such starting materials are known per se and commercially available.

A preferred embodiment of the electric lamp is characterized in that the light-absorbing medium has an amber-colored or red-colored transmission. Electric lamps that, in operation, emit amber-colored light can particularly suitably be used as an indicator lamp in vehicles. Electric lamps that, in operation, emit red light are particularly suitable as brake lights in vehicles.

The choice of selectively light-absorbing layers is limited by the requirement which, in accordance with the invention, is to be met by the steepness of the change of the spectral transmission of the light-absorbing medium. The choice of selectively light-

absorbing layers is further limited by the thermal requirements to be met by such a light-absorbing layer. Said thermal requirements include the durability of the light-absorbing medium during the service life and the resistance to changing temperatures of the lamp vessel.

5 Preferably, the light-absorbing medium has an amber-colored transmission. A particularly suitable light-absorbing medium is chromophtal yellow, chemical formula $C_{22}H_6C_{18}N_4O_2$ and C.I. (constitution number) 56280. This organic dye is also referred to as "C.I.-110 yellow pigment", "C.I. pigment yellow 137" or Bis[4,5,6,7-tetrachloro-3-oxoisindoline-1-ylidene)-1,4-phenylenediamine. An alternative
10 light-absorbing medium having an amber-colored transmission is yellow anthraquinone, chemical formula $C_{37}H_{21}N_5O_4$ and C.I. 60645. This organic dye is also referred to as "Filester yellow 2648A" or "Filester yellow RN", chemical formula 1,1'-[(6-phenyl-1,3,5-triazine-2,4diyl)diimino]bis-.

In an alternative embodiment, the light-absorbing medium has a red-colored
15 transmission and comprises, by way of example, "chromophtal red A2B" with C.I. 65300. Said organic dye is alternatively referred to as "pigment red 177", dianthraquinonyl red or as [1,1'-Bianthracene]-9,9',10,10'-tetrone, 4,4'-diamino-(TSCA, DSL).

An embodiment of the electric lamp in accordance with the invention is characterized in that the interference film comprises layers of, alternately, a first layer of a
20 material having a comparatively high refractive index and a second layer of a material having a comparatively low refractive index. The use of two materials simplifies the provision of the interference film.

A preferred embodiment of the electric lamp in accordance with the invention is characterized in that the second layer of the interference film comprises predominantly
25 silicon oxide, and the first layer of the interference film comprises predominantly a material having a refractive index which is high as compared to a refractive index of silicon oxide. Layers of silicon oxide can be provided comparatively readily using various deposition techniques.

Preferably, the interference films are $\text{TiO}_2/\text{SiO}_2$ type films or $\text{Nb}_2\text{O}_5/\text{SiO}_2$ type films and comprise preferably, 3-5 layers, most preferably 3 layers. As a consequence of the small number of layers, the interference film is simple to manufacture and the manufacturing costs of such film are relatively low. Moreover, the filter is less sensitive to oscillations in the reflection spectrum. In order to obtain a preferred high reflection maximum R_{max} , the high refractive index material preferentially has a high index of about $n=2.7$ at 500nm. The deposition of such a layer by use of mid-frequency or AC sputtering of titania is known to those skilled in the art.

The light source of the lamp may be an incandescent body, for example in a halogen-containing gas or it may be an electrode pair in an ionizable gas, for example an inert gas with metal halides, possibly with, for example, mercury as a buffer gas. An innermost gastight envelope may surround the light source. It is alternatively possible, that the outermost envelope surrounds the lamp vessel.

The interference film and the light-absorbing layer may be provided in a customary manner by means of, for example, vapor deposition (PVD: physical vapor deposition) or by a suitable sputtering technique or by means of a dip-coating or spraying process or by means of LP-CVD (low-pressure chemical vapor deposition), PE-CVD (plasma-enhanced CVD) or PI-CVD (plasma impulse chemical vapor deposition). The light-absorbing layer on the outer wall of the lamp vessel is preferably applied by means of spraying. If the light-absorbing medium forms part of the wall of the lamp vessel, then this medium is generally provided in the wall in the course of the manufacture of the lamp vessel.

It has been found that the combination of absorbing medium and interference film of the electric lamp in accordance with the invention substantially preserves its initial properties throughout the service life of the electric lamp.

These and other aspects of the invention will be apparent from and elucidated with reference to the embodiment(s) described hereinafter.

In the drawings:

Fig. 1A is a cross-sectional view of an embodiment of the electric lamp in accordance with the invention;

Fig. 1B is a side view of an alternative embodiment of the electric lamp in accordance with the invention;

Fig. 1C is a diagrammatic, perspective view of a combination of a light-absorbing medium and an interference film in accordance with the invention.

Fig. 2 shows the calculated reflection spectrum as a function of the wavelength of a 3 layer $\text{TiO}_2/\text{SiO}_2$ interference film (b) in accordance with the invention compared to a 9 layer $\text{Nb}_2\text{O}_5/\text{SiO}_2$ interference film (a);

Fig. 3 shows the calculated reflection spectrum as a function of the wavelength of a 3 layer $\text{Nb}_2\text{O}_5/\text{SiO}_2$ interference film (c) in accordance with the invention compared to a 9 layer $\text{Nb}_2\text{O}_5/\text{SiO}_2$ interference film (a).

The Figs. are purely schematic and not drawn to scale. Particularly for clarity, some dimensions are exaggerated strongly. In the Figures, like reference numerals refer to like parts whenever possible.

Fig. 1A is a cross-sectional view of an embodiment of the electric lamp in accordance with the invention. Said electric lamp has a light-transmitting lamp vessel 1, for example of glass, which is sealed in a gastight manner and which accommodates an electric element 2, in the Figure a (spiral-shaped) tungsten incandescent body, which is connected to current conductors 3 which issue from the lamp vessel 1 to the exterior. The lamp shown, which is alternatively referred to as PY21W (12 volt, 21 watt) is filled with an inert gas, for example an Ar/N_2 mixture, having a filling pressure of approximately 1 bar.

In the embodiment of the electric lamp shown in Fig. 1A, the light-absorbing medium is provided, in the form of a light-absorbing coating 6, on an outside of the lamp vessel 1 (on a wall of the lamp vessel), and an interference film 5 is provided on said light-absorbing coating (also see fig. 1B). The light-absorbing coating 6 comprises, in this case, for example a layer of the pigment (in the MTMS matrix) referred to as chromophthal yellow in a layer thickness of, for example, 2 μm . An electric lamp provided with such a light-absorbing medium emits, in operation, amber-colored light, the spectral transmission in the visible region exhibiting a transition from $T \leq 0.1$ to $T \geq 0.9$ in a wavelength range from

A2B layer emits, in operation, red-colored light. Such electric lamps are used as brake lights in vehicles, and their service life is at least substantially 1200 hours.

In an alternative embodiment of the electric lamp shown in Fig. 1A, the wall of the lamp vessel comprises the light-absorbing medium.

5 In Fig. 1A, an interference film 5 is applied to the light-absorbing medium applied to the wall of the lamp vessel 1 (the "substrate"), which interference film comprises layers of alternately a first layer of a material having a comparatively high refractive index (also see Figure 1C), for example titanium oxide (average refractive index of TiO_2 approximately 2.4-2.8) or niobium oxide (average refractive index of Nb_2O_5 approximately 2.34), and a second layer of, predominantly, silicon oxide (average refractive index 10 approximately 1.46). The $\text{TiO}_2/\text{SiO}_2$ or $\text{Nb}_2\text{O}_5/\text{SiO}_2$ interference films preferably comprise only a small number of layers, preferably 3-5 layers. However, most preferred is an interference filter comprising only 3 layers. As a result of the comparatively small number of layers, the manufacturing costs of such an interference film are comparatively low.

15 Fig. 1B is a side view of an alternative embodiment of the electric incandescent lamp in accordance with the invention. Said electric lamp comprises a quartz glass lamp vessel 11 accommodating an incandescent body as the light source 12. Current conductors 13 are connected to said light source and issue from the lamp vessel 11 to the exterior. The lamp vessel 11 is filled with a halogen-containing gas, for example hydrogen 20 bromide. At least a part of the lamp vessel 11 is covered with a light-absorbing medium 16 in the form of a light-absorbing coating, which, in this example, is formed by (a MTMS matrix-containing) chromophthal yellow or chromophthal red A2B in a layer thickness of approximately 2 μm .

In the example shown in Fig. 1B, an interference film 15 is applied to the 25 light-absorbing medium 16 and comprises layers of, alternately, a first layer of predominantly titanium oxide and a second layer of a material comprising predominately silicon oxide. The $\text{TiO}_2/\text{SiO}_2$ interference film preferably comprises a very small number of layers. Experiments have shown that an interference film comprising three layers of $\text{TiO}_2/\text{SiO}_2$ is sufficient to obtain an average reflection of 76%.

30 The lamp vessel 11 in Fig. 1B is mounted in an outer bulb 14, which is supported by a lamp cap 17 to which the current conductors 13 are electrically connected. The lamp shown is a 60 W mains-voltage lamp having a service life of at least substantially 2500 hours.

Fig. 1C is a very diagrammatic, perspective view of a combination of a light-absorbing medium and an interference film in accordance with the invention. The light-absorbing medium 6' is provided on a substrate 1' (for example the glass wall of a lamp vessel) and comprises, in this example, a layer whose thickness is approximately 1-2 μm , which is composed of comparatively small light-absorbing particles 36 (average particle size below 100 nm) which are incorporated in an optically transparent sol-gel matrix 37. An interference film 5' is applied to this light-absorbing medium 6', which is built up of alternately a first layer of a material having a high refractive index and a second layer of a material having a comparatively low refractive index. Figure 1C diagrammatically shows the direction of the incident light, indicated by means of "L", the direction of the reflected light, indicated by means of "R", and the direction of the transmitted light, indicated by means of "T".

Example

A coating comprising a light-absorbing medium in a network having an organically modified silane as the starting material is manufactured, for example, as follows:

A pigment (for example chromophthal yellow) having an average particle size below 100 nm is dispersed in a water/ethanol mixture in the presence of "disperbyk 190" as the dispersing agent. An optically clear liquid is obtained by so-called "wet ball milling" using zirconium-oxide grains.

A hydrolysis mixture is prepared by mixing methyltrimethoxysilane (MTMS), tetraethylorthosilicate (TEOS), water, ethanol and glacial acetic acid.

A mixture of the pigment dispersion and the hydrolysis mixture is used to apply a light-absorbing layer (for example 1.5-2 μm) to the lamp vessel by means of spraying. The layer is subsequently cured at 250 °C for 5-10 minutes.

Table I and II show two embodiments of combinations of a light-absorbing medium in the form of a coating including an amber or red pigment and a three-layer $\text{TiO}_2/\text{SiO}_2$ interference film having a maximum reflection of 80% or a three-layer $\text{Nb}_2\text{O}_5/\text{SiO}_2$ interference film having a maximum reflection of 70%.

Table I Embodiment of a first combination of a light-absorbing medium (pigment) and a $\text{TiO}_2/\text{SiO}_2$ interference film having a maximum reflection $R_{\text{max}} = 0.8$.

Layer	Material	Thickness (nm)
	substrate (glass)	—
1	Pigment	≈ 1800
2	TiO_2	40
3	SiO_2	91
4	TiO_2	42
	air	—

5 Table II Embodiment of a second combination of a light-absorbing medium (pigment) and a $\text{Nb}_2\text{O}_5/\text{SiO}_2$ interference film having a maximum reflection $R_{\text{max}} = 0.68$.

Layer	Material	Thickness (nm)
	substrate (glass)	—
1	pigment	≈ 1800
2	Nb_2O_5	51
3	SiO_2	99
4	Nb_2O_5	54
	air	—

Fig. 2 shows the calculated reflection spectrum as a function of the wavelength of a 3 layer $\text{TiO}_2/\text{SiO}_2$ interference film in accordance with the invention (b) compared to a 9 layer $\text{Nb}_2\text{O}_5/\text{SiO}_2$ interference film (a).

The figure shows that the reflectance of the three layer $\text{TiO}_2/\text{SiO}_2$, based on two layers of high optical index TiO_2 and one layer of SiO_2 in between, is even more reflective than the 9 layer filter consisting of alternating layers of Nb_2O_5 and SiO_2 . The light emission for the 3-layer interference filter according to the present invention will also be higher. Calculations estimate 10% increase for PY lamps.

Fig. 3 shows the calculated reflection spectrum as a function of the wavelength of a 3 layer $\text{Nb}_2\text{O}_5/\text{SiO}_2$ interference film in accordance with the invention (c) compared to a 9 layer $\text{Nb}_2\text{O}_5/\text{SiO}_2$ interference film (a).

Although the reflectivity for the 3 layer Nb_2O_5 system is slightly lower than for the higher index TiO_2 material, the expected luminous output is increased with about 20- when compared with the 9 layer $\text{Nb}_2\text{O}_5/\text{SiO}_2$ filter. Measurements show that the luminous output of lamps made with this filter show an increase of 15% with respect to the luminous output of the lamps made with the 9 layer filter, which are also shown.

It will be clear that, within the scope of the invention, many variations are possible to those skilled in the art.

The scope of protection of the invention is not limited to the examples given herein. The invention is embodied in each novel characteristic and each combination of characteristics. Reference numerals in the claims do not limit the scope of protection thereof. The use of the verb "to comprise" and its conjugations does not exclude the presence of elements other than those mentioned in the claims. The use of the article "a" or "an" in front of an element does not exclude the presence of a plurality of such elements.

CLAIMS:

1. An electric lamp comprising a light-transmitting lamp vessel (1; 11) in which a light source (2; 12) is arranged,
said electric lamp comprising a light-absorbing medium (6; 16) exhibiting a spectral transition in the visible range,
5 the spectral transmission T of light transmitted by the light-absorbing medium (6; 16) changes from $T \leq 0.15$ to $T \geq 0.75$ in a wavelength range having a width $\lambda \leq 75$ nm, at least a part of the lamp vessel (1; 11) being provided with an interference film (5; 15), characterized in that the maximum reflection R_{\max} of the interference film (5; 15) lies in the range from $0.50 \leq R_{\max} \leq 0.90$ and in that the variation in the reflection R of
10 the interference film (5; 15) in the wavelength range from $400 \leq \lambda \leq 690$ nm ranges from 0.0 to R_{\max} .
2. An electric lamp as claimed in claim 1, characterized in that the variation in the reflection R of the interference film (5; 15) in the wavelength range from 400
15 $\leq \lambda \leq 690$ nm ranges from 0.2 to R_{\max} .
3. An electric lamp as claimed in claim 1 or 2, characterized in that a wall of the lamp vessel (1) comprises the light-absorbing medium.
- 20 4. An electric lamp as claimed in claim 1 or 2, characterized in that the light-absorbing medium (6; 16) comprises a light-absorbing coating which is situated between the lamp vessel (11) and the interference film (15).
5. An electric lamp as claimed in claim 1 or 2, characterized in that the electric
25 lamp emits colored light, in operation, and has an at least substantially color-neutral appearance in the off state.
6. An electric lamp as claimed in claim 1 or 2, characterized in that the

light-absorbing medium (6; 16) comprises an amber-colored or red-colored transmission 7.

5 An electric lamp as claimed in claim 1 or 2, characterized in that the interference film (5; 15) comprises layers of alternately a first layer of a material having a comparatively high refractive index and a second layer of a material having a comparatively low refractive index.

8. An electric lamp as claimed in claim 7, characterized in that the second layer of the interference film (5; 15) comprises predominantly silicon oxide, and in that the first layer of the interference film (5) predominantly comprises a material whose refractive index is high in comparison with a refractive index of silicon oxide.

10

9. An electric lamp as claimed in claim 7, characterized in that the first layer of the interference film (5; 15) comprises a material selected from the group formed by titanium oxide, tantalum oxide, zirconium oxide, niobium oxide, hafnium oxide, silicon nitride and combinations of said materials.

15

10. An electric lamp as claimed in claim 7, characterized in that the first layer of the interference film (5; 15) comprises a material selected from the group formed by titanium oxide and niobium oxide.

20

11. An electric lamp as claimed in claim 7, characterized in that the interference film comprises 3-5 layers.

12. An electric lamp as claimed in claim 7, characterized in that the interference film comprises 3 layers.

25

ABSTRACT:

The electric lamp comprises a lamp vessel (1) which is transparent to visible light and which accommodates a light source (2). The lamp vessel (1) is covered with a combination of a light-absorbing medium (6) and an optical interference film (5) comprising layers of alternately a first layer of a material with a comparatively high refractive index and a second layer of silicon dioxide. According to the invention the maximum reflection R_{\max} of the interference film (5; 15) lies in the range from $0.50 \leq R_{\max} \leq 0.90$ and in that the variation in the reflection R of the interference film (5; 15) in the wavelength range from $400 \leq \lambda \leq 690$ nm ranges from 0.0 to R_{\max} in order to obtain an overall color neutral appearance. In operation, the electric lamp according to the invention emits colored light in the transmission mode and has a substantially color-neutral appearance in the off state.

BEST AVAILABLE IMAGES

Defective images within this document are accurate representations of the original documents submitted by the applicant.

Defects in the images include but are not limited to the items checked:

- ☒ **BLACK BORDERS**
- ☐ **IMAGE CUT OFF AT TOP, BOTTOM OR SIDES**
- ☐ **FADED TEXT OR DRAWING**
- ☐ **BLURRED OR ILLEGIBLE TEXT OR DRAWING**
- ☐ **SKEWED/SLANTED IMAGES**
- ☐ **COLOR OR BLACK AND WHITE PHOTOGRAPHS**
- ☐ **GRAY SCALE DOCUMENTS**
- ☒ **LINES OR MARKS ON ORIGINAL DOCUMENT**
- ☒ **REFERENCE(S) OR EXHIBIT(S) SUBMITTED ARE POOR QUALITY**
- ☐ **OTHER:** _____

IMAGES ARE BEST AVAILABLE COPY.

As rescanning these documents will not correct the image problems checked, please do not report these problems to the IFW Image Problem Mailbox.
